

SHORT REFLECTION

What I learnt

In this project I gained a much more deeper understanding of concepts that were a bit difficult for me to understand during the class session. I learnt how to use classes and inheritance in Python and I successfully managed to create a parent class known as Assignment and two child classes that are Homework and Examination. I also learnt how to store objects in a list using the GradeTracker class and using functions and a menu so that the user can add, list and filter all their assignments. I also understand better how the while loop keeps the program running until the user chooses to exit and also how if statements can help the menu work accordingly.

Challenges I faced

The first challenge I faced was during the repository cloning where I used and started the assignment with a different email and later on got confused on whether I had to change the email or simply restart the entire work. The biggest challenge I faced was understanding how inheritance works since this topic was still a bit hard for me especially with the super() method. This caused me to make a lot of mistakes when creating the Homework and Examination classes.

Another challenge was connecting the menu options to the GradeTracker object. Most times the program crashed because I forgot to create the tracker object or called the method in the wrong way. And lastly, I found it difficult to write the filter function correctly, especially matching the due date.

How I intend to improve it

If I had more time, I would add better input validation so that my program does not collapse if a person enters wrong data in the program. I would also improve the summary to show average marks per subject and give warnings when a score is very low. And lastly, I would edit my work by adding more comments in order to get an output that is cleaner and easier to understand
